

DIHWorld Audio Sidechain Routing Guide

Current: 2026-10-04 Scope: DIHWorld Audio 42-plugin suite

Sidechain concept

A sidechain is an external control signal. The key tells the inserted DIHWorld Audio plugin when to react, but the key is not mixed into the program output by the plugin. In Logic Pro, choose the key from the native **Side Chain** menu above the plugin editor. In other VST3 hosts, enable the auxiliary input and confirm that the detector responds before increasing depth.

Current plugin roster and placement

Plugin	Primary placement	Secondary / key source	Expected behavior
ANUBIS	Dialogue, drums, vocal cleanup, room tracks	Trigger, vocal, drum transient, or rhythmic key	Gate/expander opens or ducks from the key.
TEHUTI	Bass, music bed, pad, FX return, or mix element	Kick, vocal, hats, or drum bus	Low/mid/high spectral ducking creates frequency-selective space.
MARIANA	Bass or low-end support track	Kick or low-frequency key	Added low-end layer follows the key while the dry bass remains controlled.
MONOLITH	Bass bus, low-end bus, or heavy tone return	Kick or low-frequency key	Wet low-frequency field makes room for the keyed source.
NTRPL	Music, bass, texture, or rewrite layer	Kick, rhythm key, or vocal	Alternate rewrite layer ducks while the main program stays present.
DrumKrushGlue	Drum track or drum bus	Kick, snare, or transient bus	Key controls impact/glue intensity without audible key bleed.
SacredVerb	Reverb aux, spatial bus, or wet return	Vocal, kick, snare, or pattern key	Wet reverb / Solfeggio return ducks while the dry path stays intact.

SacredVerb is the current wet-return / spatial sidechain route.

Basic routing schematic

PROGRAM TRACK -> DIHWorld insert -> stereo output KEY TRACK -> DAW native Side Chain selector -> detector input

The key is detector/control information only. Do not mix it into the destination output.

Logic Pro setup

1. Insert the sidechain processor on the track, bus, or return that must move. 2. Choose the key source from Logic's **Side Chain** selector. 3. Play the key and target together; the key track must contain real level. 4. Enable the plugin's KEY / sidechain function where provided. 5. Adjust duck depth and recovery while listening in context. 6. Enable Gain Match where provided, then compare with bypass at equal loudness.

SacredVerb wet-return example

Place SacredVerb on a 100% wet reverb or spatial return. Route a foreground vocal, kick, snare, or full pattern to its key input. Increase **WET DUCK** only until the foreground source is clear; lengthen recovery if the tail chatters. The dry program remains outside the reduction multiplier, and key audio is never mixed into the return.

Troubleshooting

Symptom	Check
No movement	Confirm the host Side Chain / auxiliary input is assigned and the key meter moves.
Audible key bleed	The key should feed the detector only; remove any direct key-to-output route in the DAW.
Pumping or chatter	Reduce duck amount or lengthen Speed / Recovery / Release.
Target loses identity	Prefer layer-only ducking (MARIANA, MONOLITH, NTRPL, DrumKrushGlue, SacredVerb) or reduce ANUBIS Range.
Output sounds louder, not better	Enable Gain Match where available and compare with bypass at equal loudness.
